

# hypothesis Testing

### **Hypothesis**

My insights says the the best selling time in the whole world is from 9 am to 4 o clock

let's create two sets of data

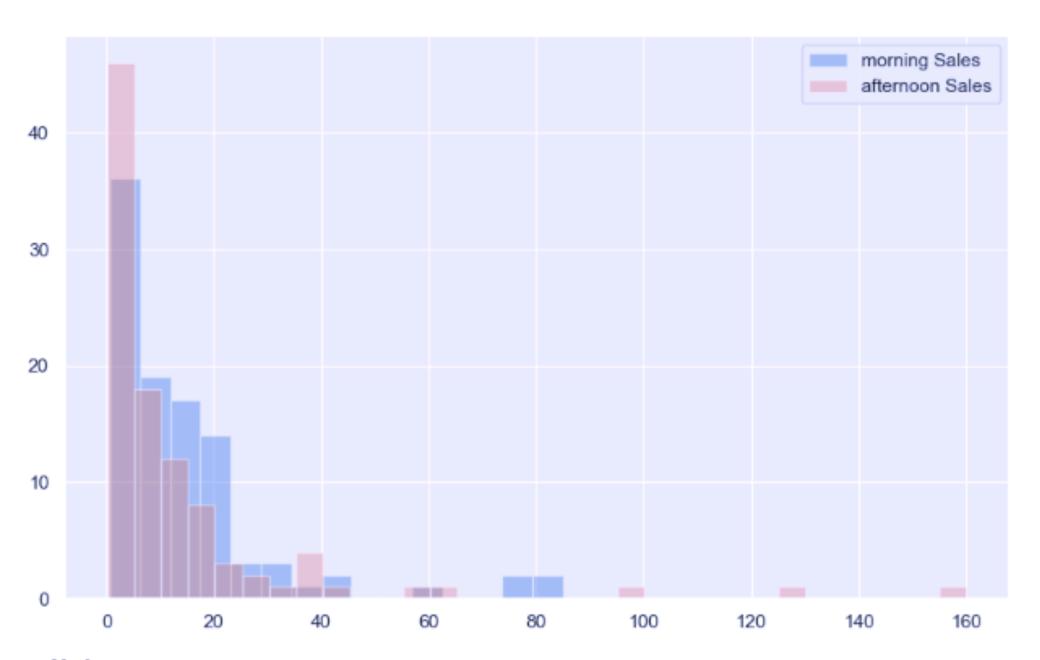

morning Sales: If time is from 8 to 17

afternoon Sales: If time is from 18 to 7

Take a sample of 100 record in each dat

Set alpha (set alpha = 0.05)

'HO': "Total price does not increase for Sale", 'Hl': "Total price increases for Large Sale"

#### Variance

# # ANSWER print("Low sales:", part2.var())

High sales: 285.81379256565657 Low sales: 566.5941854141413

#### Calculate Standard Deviation

```
print("High sales:", part1.var()) std = np.sqrt(( part1.var() + part2.var()) / 2)
                                print('standard deviation is:', std)
```

standard deviation is: 20.644708498545068

#### Calculate test statistic

```
t = (part1.mean() - part2.mean()) /(std *np.sqrt(2/N))
print('t:', t)
```

t: 0.23311391163962647

## Calculate Degree of Freedom

```
df = 2 * N - 2
df
```

198

#### Find the p-value

```
p = 1 - stats.t.cdf(abs(t), df=df)
print("t = " + str(t))
print("p = " + str(2 * p))
```

t = 0.23311391163962647 p = 0.815913764073509
